The lead-acid battery is a type of rechargeable battery first invented in 1859 by French physicist Gaston Planté. It is the first type of rechargeable battery ever created. Compared to modern rechargeable batteries, lead-acid batteries have relatively low energy density. Despite this, their ability to supply high surge currents means that the cells have a relatively large power-to-weight ratio.

The batteries were then discharged at 1,500mA to 3.0V/cell, and the cycle was repeated. The expected capacity loss of Li-ion batteries was uniform over the delivered 250 cycles and the batteries performed as expected. Figure 1: Capacity drop as part of cycling [1] Eleven new Li-ion were tested on a Cadex C7400 battery analyzer.

Electrochemical impedance spectroscopy (EIS) is a widely applied non-destructive method of characterisation of Li-ion batteries. Despite its ease of application, there are inherent challenges in ensuring the quality and reproducibility of the measurement, as well as reliable interpretation and validation of impedance data.

After that it read normal again. Apparently a dying battery can make the multi meter become optimistic. Sulfation is something that happens more in peoples' imagination than in lead-acid batteries. Batteries that are deep cycled and/or kept on a relatively high rate of charge wear out due to positive plate corrosion and active material shedding.
